1 Example code for using session.Session

Note: This notebook covers several relevant methods of the `Session` and `Stim` objects, detailing some of their arguments, as well. For more details, take a look at the docstring associated with a method of interest.

Import notes:

- These packages should be present if installing the conda environment from `osca.yml`.
- `util` is a Github repo of mine, and the correct branch `osca_mult` is automatically installed from `osca.yml`.

- **Potential updates:** Errors internal to the codebase involving `util` code and occurring *after* new changes have been pulled from the `OpenScope_CA_Analysis` repo *may* be due to an update of the `osca_mult` branch of `util` that breaks backwards compatibility.
  Though I will try to avoid this, check whether there are updates to the utility, if an error occurs, and consider updating your installation, e.g., by running, from the command line: `pip install -U util-colleenjg`

[1]:
```
import sys
from pathlib import Path

from matplotlib import pyplot as plt
import numpy as np
import pandas as pd

sys.path.extend([".", ".."])
from analysis import session
from sess_util import sess_gen_util, sess_plot_util
from util import gen_util, logger_util, plot_util
```

1.1 Plot formatting

If you wish to use the same formatting style as I do:

[2]:
```
plot_util.linclab_plt_defaults()
```

1.2 Set paths to main data directory and the mouse dataframe

1.2.1 Data directory

The data directory should contain the session data, either in its **original format** or in **NWB format**.
* If in NWB format (production data, only), `datadir` should be a directory that contains the data in NWB format, at any depth.
* If using the data in its original format, `datadir` should specifically be the directory right before the data is split into `prod` (production) and `pilot` (pilot) data.

[3]:
```
datadir = Path("..", "..", "data", "OSCA")
```

1.2.2 Mouse dataframe

The mouse dataframe, contains the metadata for each session, including its 9-digit `sessid`, the `mouse_n`, `sess_n`, etc.

[4]:
```
mouse_df = pd.read_csv(Path("..", "mouse_df.csv"))
```

Mouse dataframe columns:
* **`sessid`**: Unique session ID (9-digit)
* **`dandi_session_id`**: Dandiset session ID for data in NWB format.
* **`mouse_n`**: Mouse number
* **`mouseid`**: Unique mouse ID (6-digit)
* **`date`**: Recording date
* **`depth`**: Recording depth (um)
* **`plane`**: Recording plane ("dend" or "soma")
* **`line`**: Cell line ("L2/3-Cux2" or "L5-Rbp4")
* **`runtype`**: Type of session ("pilot" or "prod"). Only production data is available in NWB dataset.
* **`sess_n`**: Session number
* **`nrois`**: Number of valid ROIs (see ***Note***)
* **`nrois_tracked`**: Number of ROIs tracked across sessions (-1 for sessions with no tracking).
* **`nrois_all`**: Same as **`nrois`**, but including bad (non valid) ROIs.
* **`nrois_allen`**: Number of valid ROIs when using the `allen` segmentation for dendritic ROIs, instead of the `extr` segmentation (see ***Note***).
* **`nrois_allen_all`**: Same as **`nrois_allen`**, but including bad (non valid) ROIs.
* **`pass_fail`**: Whether the session passed (`P`) or failed (`F`) quality control.
* **`all_files`**: Whether all files are available for the session (original data format).
* **`any_files`**: Whether any files are available for the session (original data format).
* **`incl`**: Whether the session can be included in analyses (looser criterion than **`pass_fail`**).
* **`stim_seed`**: Seed used to initialize stimuli for the session, during recording.
* **`notes`**: Any notes on the session.

Note: The `allen` segmentations are used for all **somatic** data. The `extr` segmentations are preferred for all **dendritic** data. For this reason, the `allen` segmentation for **dendritic** data is ***not included*** in the NWB dataset. See **section 6** for details on `allen` and `extr` ROI mask types.

1.3 1. Basics of initializing a Session object

Sessions can be intialized with their 9-digit `sessid`:

[6]:
```
sess = session.Session(764704289, datadir=datadir, mouse_df=mouse_df)
```

or with their `mouse_n`, `sess_n` and `runtype`:

[7]:
```
sess = session.Session(mouse_n=4, sess_n=1, runtype="prod", datadir=datadir,␣
↪mouse_df=mouse_df)
```

1.3.1 Data format is identified automatically

During initialization, the code looks first for the session data in NWB format, under its `dandi_session_id`. If it doesn't find it, it looks for the data in its original format. If neither are found, an error is thrown.

1.3.2 Loading the data after initialization.

After creating the session, you must run `self.extract_info()`. This wasn't amalgamated into the `__init__` to reduce the amount of information needed to just create a session object.

1.3.3 Loading ROI/running/pupil info

You can load this information when you call `self.extract_info()` or manually later by calling `self.load_roi_info()`, `self.load_run_data()` and `self.load_pup_data()`.

[8]:
```
sess.extract_info(full_table=False, roi=True, run=True, pupil=True)
```

```
Loading stimulus and alignment info…
Loading ROI trace info…
Loading running info…
    WARNING: Session 760260459: 349 dropped running frames (~0.1%) (in pre-
processing).
Loading pupil info…
```

1.3.4 Stimulus dataframe

The stimulus dataframe, stored under `sess.stim_df`, details the stimulus feature for each segment of the presentation.
A **segment** is the minimal subdivision of the stimulus presentation: **0.3 sec** for the Gabor stimulus, and **1s** for the visual flow, and grayscreen stimuli.

If a feature **does not apply** to certain segments (e.g., `gabor_number` for visual flow stimulus segments), the values for those segments will be `None`, `NaN` or `[]`, depending on the column's datatype.

Missing columns: Note that a few columns are missing, since the session was loaded with `full_table=False`. * `"gabor_orientations"`: Specific orientation of each Gabor patch, for each segment. * `"square_locations_x"`: Specific x location of each visual flow square, at **each frame** of each segment. * `"square_locations_y"`: Specific y location of each visual flow square, at **each frame** of each segment.

This is primarily to save memory, when loading a session, as this information is not typically needed. To load all columns, re-run `sess.extract_info()` with `full_table=True`. Data that is already loaded will not be re-loaded.

[9]:
```
sess.stim_df
```

```

1.3.5 Stimulus objects

Once `sess.extract_info()`, each Session object now contains `Stim` objects.

These come in one of three subclasses: `Gabors`, `Visflow`, `Grayscr`, and can be accessed with: `sess.stims`, `sess.gabors`, `sess.visflow`, `sess.grayscr`.

The the `Stim` object `stim`, the Session object can be accessed with `stim.sess`.

[10]:
```python
print(f"number of rois          : {sess.get_nrois()}")
print(f"mouse number            : {sess.mouse_n}")
print(f"mouse ID                : {sess.mouseid}")
print(f"gabor object            : {sess.gabors}")
print(f"2p frames per sec       : {sess.twop_fps:.2f}")
print(f"stimulus frames per sec: {sess.stim_fps:.2f}")
```

```
number of rois          : 90
mouse number            : 4
mouse ID                : 411771
gabor object            : Gabors (stimulus from session 760260459)
2p frames per sec       : 30.08
stimulus frames per sec: 59.95
```

1.4 2. Retrieving data of interest

1.4.1 Identifying stimulus segments of interest

From a `Session`'s `Stim`, you can get a list of segments that fit a specific criterion, e.g. **U segments** (unexpected, 3rd Gabor frame).

[11]:
```
gab_seg_ns = sess.gabors.get_segs_by_criteria(gabk=16, gabfr=3, unexp=1,␣
↪by="seg")
```

1.4.2 Identifying frame numbers of interest, to index the data

Then, you can retrieve the exact frame numbers that match these segments.

Specifically, you can access: * `twop` frame numbers, which index the two-photon data and pupil data, and * `stim` frame numbers, which index the running data.

Note: When retrieving the frame numbers, specifying `ch_fl` (check flanks) ensures that only frame numbers whose flanks are within the recording are returned. In other words, any frame number too close to the start or end of the recording (based on `pre`/`post` values), will be dropped.

[12]:
```
pre = 1.0
post = 1.0
twop_fr_ns = sess.gabors.get_fr_by_seg(gab_seg_ns, start=True, ch_fl=[pre,␣
↪post], fr_type="twop")["start_frame_twop"]
stim_fr_ns = sess.gabors.get_fr_by_seg(gab_seg_ns, start=True, ch_fl=[pre,␣
↪post], fr_type="stim")["start_frame_stim"]
```

1.4.3 Retrieving the data of interest

You can now get the **ROI / running / pupil data** corresponding to these reference frames and the specified `pre` / `post` periods (in sec).

[13]:
```
roi_data_df = sess.gabors.get_roi_data(twop_fr_ns, pre, post, scale=True)
run_data_df = sess.gabors.get_run_data(stim_fr_ns, pre, post, scale=True)
pup_data_df = sess.gabors.get_pup_diam_data(twop_fr_ns, pre, post, scale=True)
```

1.4.4 Retrieving data statistics of interest

You can also directly obtain statistics on the data of interest.

[14]:
```
roi_stats_df = sess.gabors.get_roi_stats_df(
    twop_fr_ns, pre, post, integ=True, stats="mean", error="sem", byroi=False
)
roi_stats_df
```

[14]:
```
datatype                 roi_traces
bad_rois_removed                yes
scaled                           no
baseline                         no
```

```
integrated                    yes
smoothing                      no
fluorescence                  dff
general ROIs sequences
stats   None stat_mean   0.062516
             error_SEM   0.017370
```

1.4.5 Using hierarchical dataframes

Data and statistics are returned in a hierarchical dataframe with **columns** and **indices**.

This has the advantage of allowing metadata to be stored in dummy columns, however extracting data from these dataframes can be tricky, syntactically.

[15]:
```
roi_data_df
```

[15]:
```
datatype                       roi_traces
bad_rois_removed                      yes
scaled                                yes
baseline                               no
integrated                             no
smoothing                              no
fluorescence                          dff
ROIs sequences time_values
0    0         -1.000000        -0.338172
               -0.966102         0.155122
               -0.932203         0.150821
               -0.898305         0.053135
               -0.864407        -0.100729
…                                   …
102  81         0.864407         0.297796
                0.898305        -0.031714
                0.932203         0.339743
                0.966102         0.524661
                1.000000        -0.289968

[442800 rows x 1 columns]
```

To **extract a numpy array** with the correct dimensions from a hierarchical dataframe, you can use the following utility function: `gen_util.reshape_df_data()`.

Here, each index level, then column level is turned into a new axis, **i.e. ROIs x sequences x time_values** (In this case, `squeeze_cols` is set to True to prevent each dummy column from becoming its own axis.)

[16]:
```
roi_data = gen_util.reshape_df_data(roi_data_df, squeeze_cols=True)
print("ROI data shape: {} ROIs x {} sequences x {} time values".
 ↪format(*roi_data.shape))
```

```
ROI data shape: 90 ROIs x 82 sequences x 60 time values
```

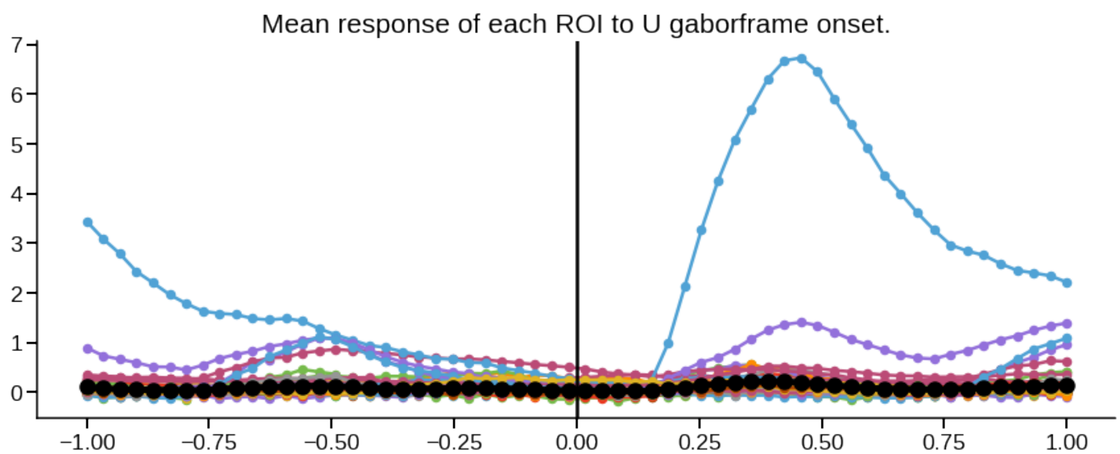
You can also retrieve the time stamps for each frame.

[17]:
```
xran = roi_data_df.index.unique("time_values")
```

1.4.6 Visualizing the data

Finally, we can plot each ROIs mean activity across sequences, as well as a mean across ROIs.

[18]:
```
fig, ax = plt.subplots(1, figsize=(12, 5))
_ = ax.plot(xran, np.mean(roi_data, axis=1).T, marker=".") # mean per ROI
_ = ax.plot(xran, np.mean(np.mean(roi_data, axis=1).T, axis=1),
            lw=5, c="k", marker="o") # mean across ROIs
_ = ax.axvline(0, c="k")
_ = ax.set_title("Mean response of each ROI to U gaborframe onset.")
```



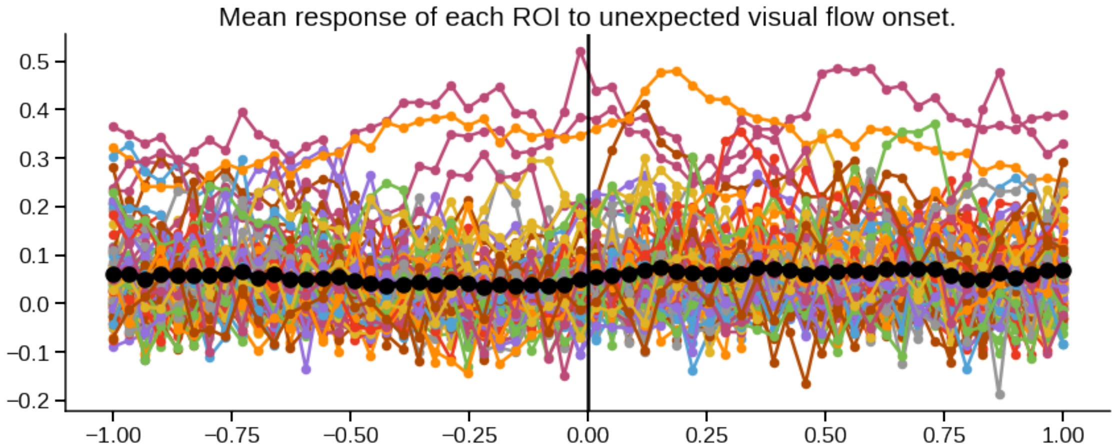
1.4.7 The same steps apply for Visflow

[19]:
```
visflow_seg_ns = sess.visflow.get_segs_by_criteria(visflow_size=128, unexp=1,␣
 ↪remconsec=True, by="seg")

pre = 1.0
post = 1.0
twop_fr_ns = sess.visflow.get_fr_by_seg(
    visflow_seg_ns, start=True, ch_fl=[pre, post],␣
 ↪fr_type="twop")["start_frame_twop"]

roi_data_df = sess.visflow.get_roi_data(twop_fr_ns, pre, post, scale=True)
roi_data = gen_util.reshape_df_data(roi_data_df, squeeze_cols=True)
xran = roi_data_df.index.unique("time_values")
```

```
fig, ax = plt.subplots(1, figsize=(12, 5))
_ = ax.plot(xran, np.mean(roi_data, axis=1).T, marker=".") # mean per ROI
_ = ax.plot(xran, np.mean(np.mean(roi_data, axis=1).T, axis=1),
            lw=5, c="k", marker="o") # mean across ROIs
_ = ax.axvline(0, c="k")
_ = ax.set_title("Mean response of each ROI to unexpected visual flow onset.")
```



1.5 3. Tracked ROIs

ROI tracking was performed on the `production` data.
At any point, it is possible to **restrict the data returned** to only the tracked ROIs, called `sess.set_only_tracked_rois(True)`.

[20]:
```
sess.set_only_tracked_rois(True)
```

Here, we retrieve the data, **integrated over each sequence**.

[21]:
```
tracked_roi_data_df = sess.visflow.get_roi_data(twop_fr_ns, pre, post,␣
↪scale=True, integ=True)
```

The dataframe returned contains data only for tracked ROIs.

[22]:
```
tracked_roi_data_df
```

[22]:
```
datatype          roi_traces
bad_rois_removed         yes
scaled                   yes
baseline                  no
integrated               yes
smoothing                 no
fluorescence             dff
ROIs sequences
```

```
28   0           0.101591
     1           0.188843
     2          -0.072082
     3           0.685275
     4           0.033439
…                   …
22   27          0.026887
     28          0.523182
     29         -0.039192
     30         -0.059955
     31          0.080472

[1504 rows x 1 columns]
```

1.5.1 Extracting tracked ROI data correctly (!)

Importantly, the ROIs are now sorted in their tracking order, which ensures that they are correctly aligned across sessions.
As a result, the **"ROIs" index** may no longer be in increasing order, like in this example.

[23]:
```
roi_ns_ordered = tracked_roi_data_df.index.unique("ROIs").to_numpy()
print(f"ROI numbers, ordered for tracking:\n{', '.join([str(roi_n) for roi_n in␣
↪roi_ns_ordered])}")
```

```
ROI numbers, ordered for tracking:
28, 69, 90, 2, 55, 7, 5, 73, 101, 16, 93, 85, 84, 17, 15, 18, 29, 26, 13, 48, 1,
74, 25, 87, 72, 88, 89, 76, 0, 78, 67, 57, 62, 50, 42, 41, 43, 14, 32, 6, 45,
46, 98, 44, 27, 34, 22
```

To **ensure that the tracked ROI order is preserved** when extracting the data, the safest option is to use the utility function introduced above, i.e. `gen_util.reshape_data_df()`. It will ensure that the order is preserved.

[24]:
```
tracked_roi_data = gen_util.reshape_df_data(tracked_roi_data_df,␣
↪squeeze_cols=True)
print("Tracked ROI data shape using the correct method, i.e., gen_util.
↪reshape_df_data()"
      "\n{} ROIs x {} sequences".format(*tracked_roi_data.shape))
```

```
Tracked ROI data shape using the correct method, i.e.,
gen_util.reshape_df_data()
47 ROIs x 32 sequences
```

Do not use the `.unstack()` method for hierarchical dataframes!

Even though the `.unstack()` method is typically a convenient way to extract a 2D array from a hierarchical dataframe, it will cause major problems here. Specifically, `.unstack()` internally triggers a resorting of the hierarchical indices. Thus, using it will completely mess up the tracked ROI order.

[25]:
```
tracked_roi_data_wrong = tracked_roi_data_df.unstack().to_numpy()
print("Tracked ROI data shape using the wrong method, i.e., .unstack()"
      "\n{} ROIs x {} sequences".format(*tracked_roi_data_wrong.shape))
```

```
Tracked ROI data shape using the wrong method, i.e., .unstack()
47 ROIs x 32 sequences
```

As you can see, the dimensions are still correct. However, the **ROI sorting is actually lost!**

For example, **ROI #5**, which should appear at index 6 in the array, is now at index 3.

[26]:
```
roi_idx_6_data = tracked_roi_data[6, :10]
print(f"Data for the tracked ROI at index 6, when using the correct method: i.e.
↪, gen_util.reshape_df_data()"
      f"\n{', '.join([f'{val:.3f}' for val in roi_idx_6_data])} ...")
```

```
Data for the tracked ROI at index 6, when using the correct method: i.e.,
gen_util.reshape_df_data()
0.005, 0.024, -0.050, -0.553, 0.629, -0.051, -0.057, 0.071, -0.003, -0.067 …
```

[27]:
```
roi_idx_6_data_wrong = tracked_roi_data_wrong[6, :10]
print(f"Data for the tracked ROI at index 6, when using the wrong method: i.e.,␣
↪.unstack()"
      f"\n{', '.join([f'{val:.3f}' for val in roi_idx_6_data_wrong])} ...")
```

```
Data for the tracked ROI at index 6, when using the wrong method: i.e.,
.unstack()
0.053, 0.191, 0.232, -0.004, -0.008, 0.060, 0.083, -0.031, 0.015, 0.024 …
```

[28]:
```
roi_idx_3_data_wrong = tracked_roi_data_wrong[3, :10]
print(f"Data for the tracked ROI that should be at index 6 is instead at index␣
↪3,\n"
      "when using the wrong method: i.e., .unstack()"
      f"\n{', '.join([f'{val:.3f}' for val in roi_idx_3_data_wrong])} ...")
```

```
Data for the tracked ROI that should be at index 6 is instead at index 3,
when using the wrong method: i.e., .unstack()
0.005, 0.024, -0.050, -0.553, 0.629, -0.051, -0.057, 0.071, -0.003, -0.067 …
```

1.5.2 Reset the session to start using all ROIs, again

[29]:
```
sess.set_only_tracked_rois(False)
```

1.6 4. Additional tips on indexing a hierarchical dataframe

[30]:
```
# getting columns
roi_data_series = roi_data_df["roi_traces"]
```

```
# getting specific ROIs, from their IDs, e.g. (0, 3, 5)
roi_data_specific_rois = roi_data_df.loc[([0, 3, 5])]

# getting specific sequences (0, 3, 5) for all ROIs <- second order index, so
↪requires a pandas slice
roi_data_specific_seqs = roi_data_df.loc[(pd.IndexSlice[:, [1, 20, 21]]), ]

# using both index and columns
roi_data_specific = roi_data_df.loc[(pd.IndexSlice[[0, 3, 5], [1, 20, 21],
↪-1]), ("roi_traces", "yes")]
roi_data_specific
```

[30]:
```
scaled                                 yes
baseline                                no
integrated                              no
smoothing                               no
fluorescence                           dff
ROIs sequences time_values
0    1         -1.0            -0.183646
     20        -1.0             0.013693
     21        -1.0            -0.091127
3    1         -1.0             0.221201
     20        -1.0             0.347209
     21        -1.0            -0.163844
5    1         -1.0            -0.243460
     20        -1.0            -0.422120
     21        -1.0             0.203985
```

1.7 5. Retrieving several Session objects, based on criteria

1.7.1 Identifying mice or session IDs to omit (pilot data only)

`sess_gen_util.all_omit()` allows keeping track of **which session IDs or mice must be left out**.

This actually **only applies to pilot data**, where some mice did not see all the stimuli of interst, and one session has incomplete data.
For the `prod` data, the lists are empy.

[31]:
```
omit_sess, omit_mice = sess_gen_util.all_omit(runtype="prod")
```

1.7.2 Retrieving mouse / session numbers and IDs that fit specific criteria

`sess_gen_util.get_sess_vals()` can be used to retrieve information for sessions that meet certain criteria.
e.g., **session number 1, 2 or 3**, **production**, **dendritic plane**

[32]:
```
mouse_ns, sess_ns, sessids = sess_gen_util.get_sess_vals(
    mouse_df, ["mouse_n", "sess_n", "sessid"], sess_n=[1, 2, 3],␣
 ↪runtype="prod", plane="soma", omit_sess=omit_sess,
    omit_mice=omit_mice, unique=False)
```

[33]:
```
print("\n".join([f"mouse {m:2}: {sid} (session {n})" for m, sid, n in␣
 ↪zip(mouse_ns, sessids, sess_ns)]))
```

```
mouse  1: 758519303 (session 1)
mouse  1: 759189643 (session 2)
mouse  1: 759660390 (session 3)
mouse  3: 761624763 (session 1)
mouse  3: 761944562 (session 2)
mouse  3: 762250376 (session 3)
mouse  4: 760260459 (session 1)
mouse  4: 760659782 (session 2)
mouse  4: 761269197 (session 3)
mouse  7: 777496949 (session 1)
mouse  7: 778374308 (session 2)
mouse  7: 779152062 (session 3)
mouse 12: 826659257 (session 1)
mouse 12: 827300090 (session 2)
mouse 12: 828475005 (session 3)
mouse 13: 832883243 (session 1)
mouse 13: 833704570 (session 2)
mouse 13: 834403597 (session 3)
```

1.7.3 Loading the sessions

`sess_gen_util.init_sessions()` can be used to **initialize the sessions** and **extract the requested data**.

[34]:
```
soma_sessions = sess_gen_util.init_sessions(
    sessids[:3], datadir, mouse_df, full_table=False, omit=True, runtype="prod",
    roi=True, run=True
)

dend_sessions = sess_gen_util.init_sessions(
    [764704289], datadir, mouse_df, full_table=False, omit=True, runtype="prod",
    roi=True, run=True
)
```

```

```

1.7.4 Using the loaded sessions

Now, one can run through the sessions, and run whatever analysis is needed.

Note here that, when calling `stim.get_segs_by_criteria()`, **features that do not apply to the stimulus** (e.g., `gabfr` for the `visflow` stimulus) **are simply ignored**.

[35]:
```
for sess in soma_sessions + dend_sessions:
    print(f"Session ID: {sess.sessid} (mouse {sess.mouse_n}, session {sess.
↪sess_n})")
    for stimtype in ["visflow", "gabors"]:
        stim = sess.get_stim(stimtype)
        segs = stim.get_segs_by_criteria(
            visflow_size=128, unexp=1, gabk=16, gabfr=3, by="seg",
            remconsec=(stimtype == "visflow")
            )
        print(f"    {stimtype}: {len(segs)} sequences")
```

```
Session ID: 758519303 (mouse 1, session 1)
    visflow: 31 sequences
    gabors: 94 sequences
Session ID: 759189643 (mouse 1, session 2)
```

```
    visflow: 34 sequences
    gabors: 90 sequences
Session ID: 759660390 (mouse 1, session 3)
    visflow: 33 sequences
    gabors: 105 sequences
Session ID: 764704289 (mouse 6, session 1)
    visflow: 33 sequences
    gabors: 96 sequences
```

1.8 6. Retrieving ROI masks from session.

Boolean ROI masks can be obtained for each Session.

1.8.1 Dendritic mask types

For **dendritic sessions**, the Session is built to assume that `extr` (not `allen`) ROI data is to be used. This can be checked by checking `self.dend`. As long as `self.dend` is properly set, the correct ROI data and masks will be loaded.

The `allen` masks were extracted with a pipeline tailored to somatic ROIs, and are therefore not preferred for dendritic data.
In contrast, the `extr` masks were extracted with the EXTRACT pipeline, which specifically enables dendrite-shaped ROIs to be identified.

Note that, for this reason, ***only the extr dendritic ROIs and masks*** are included in the data in NWB formatted data.

[36]:
```
dend_sess = dend_sessions[0]
print(f"Dendritic session, ROI type: {dend_sess.dend}")

soma_sess = soma_sessions[0]
print(f"Somatic session, ROI type: {soma_sess.dend}")
```

```
Dendritic session, ROI type: extr
Somatic session, ROI type: allen
```

1.8.2 Loading masks

Masks can be loaded as follows, with dimensions: **ROI x height x width**, retrieving only masks for ROIs that are valid (when evaluated by their dF/F traces).

Note that **if sessions are set to use only tracked ROIs**, as described above, only masks for the tracked ROIs (sorted in the tracking order) will be returned.

[37]:
```
dend_mask = dend_sess.get_roi_masks()
soma_mask = soma_sess.get_roi_masks()
```

In most functions, by default, ROIs that are considered **bad (non valid)** are automatically removed (`rem_bad=True`).
Note that, **for the NWB data**, the ***bad ROIs were removed altogether***.

These ROIs either:
(1) contain NaN/Infs values or
(2) have been deemed too noisy.

If, for whatever reason, **all masks are needed**, including those for the bad ROIs,
(1) ensure that the session is currently set to return all ROI data, with `sess.only_tracked_rois(False)`, then
(2) call `self.get_roi_masks(rem_bad=False)`.

Of course, as explained above, if using the NWB data, there are no bad ROIs.

[38]:
```
dend_sess.set_only_tracked_rois(False)
soma_sess.set_only_tracked_rois(False)

dend_mask_all = dend_sess.get_roi_masks(rem_bad=False)
soma_mask_all = soma_sess.get_roi_masks(rem_bad=False)
```

1.8.3 Bad ROIs

When using the data in its original format, one can get a list of bad ROIs, by using `self.get_bad_rois()`

[39]:
```
dend_nan_masks = np.asarray(dend_sess.get_bad_rois(fluor="dff"))
soma_nan_masks = np.asarray(soma_sess.get_bad_rois(fluor="dff"))

dend_valid = np.ones(len(dend_mask_all))
dend_valid[dend_nan_masks] = 0

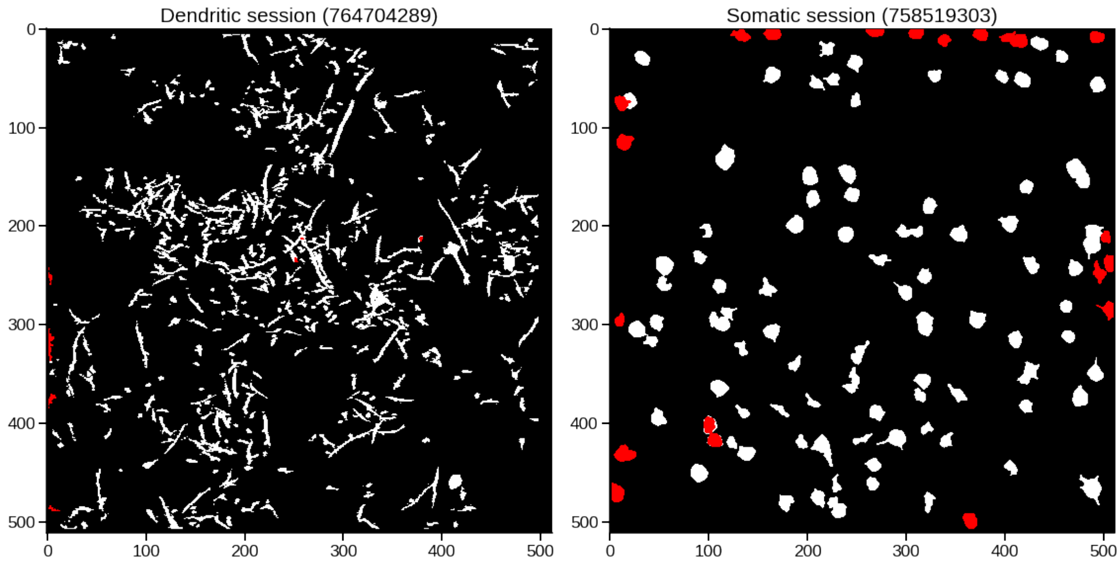
soma_valid = np.ones(len(soma_mask_all))
soma_valid[soma_nan_masks] = 0
```

1.8.4 Visualizing ROI masks

`sess_plot_util.plot_ROIs()` can be used to visualize ROIs, where specific ROIs can be set to red using a `valid_mask`.

[40]:
```
fig, ax = plt.subplots(1, 2, figsize=(16, 9))
sess_plot_util.plot_ROIs(ax[0], dend_mask_all, valid_mask=dend_valid)
_ = ax[0].set_title(f"Dendritic session ({dend_sess.sessid})")

sess_plot_util.plot_ROIs(ax[1], soma_mask_all, valid_mask=soma_valid)
_ = ax[1].set_title(f"Somatic session ({soma_sess.sessid})")
```

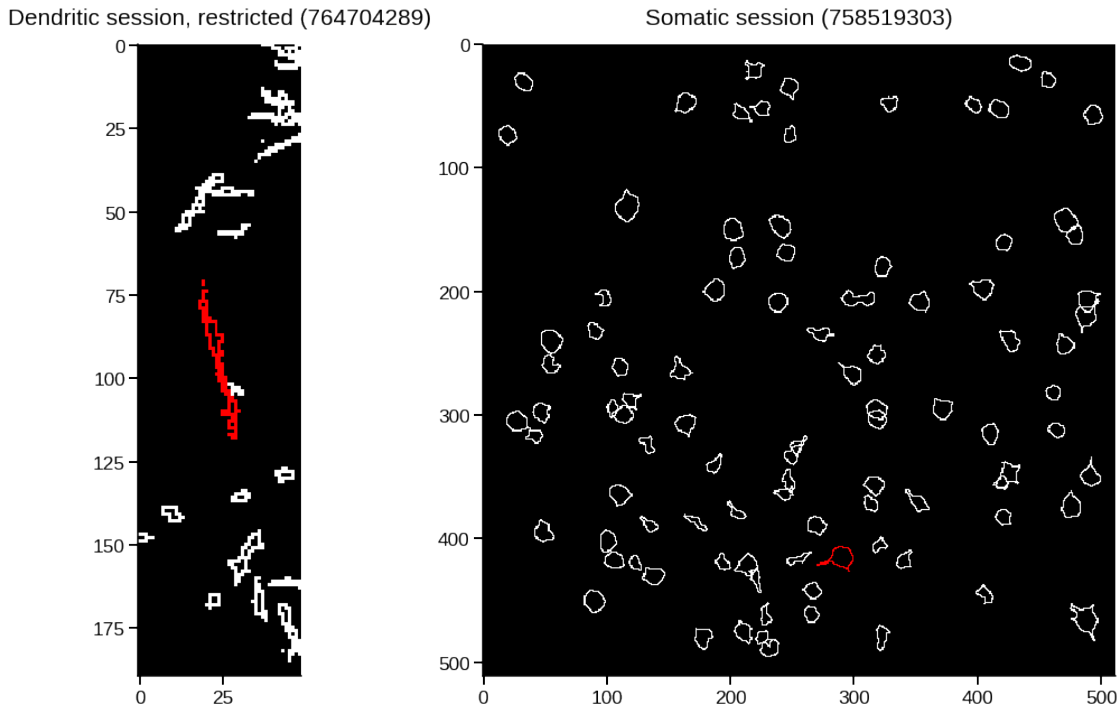


1.8.5 Visualizing ROI mask contours

`sess_plot_util.plot_ROI_contours()` can be used to visualize ROI contours, optionally restricted to around an ROI of interest.

[41]:
```
fig, ax = plt.subplots(1, 2, figsize=(16, 9))
sess_plot_util.plot_ROI_contours(ax[0], dend_mask, outlier=490, restrict=True)
_ = ax[0].set_title(f"Dendritic session, restricted ({dend_sess.sessid})", y=1.
↪02)

sess_plot_util.plot_ROI_contours(ax[1], soma_mask, outlier=30)
_ = ax[1].set_title(f"Somatic session ({soma_sess.sessid})", y=1.02)
```



1.9 7. Last notes

There is much more to the codebase, and even to the `Session` and `Stim` objects, and almost all functions and methods are thoroughly documented.

When looking to implement a new analysis, consider checking to see whether relevant functions have already been implemented in:
* `analysis/session.py`
* `analysis/basic_analys.py`
* `sess_util/sess_gen_util.py`

1.9.1 Methods/properties attached to `Session` and `Stim` objects.
